Benchmarking Air Emissions
Of the 100 Largest Electric Power Producers in the United States

July 2021
Data Downloads at: www.mjbradley.com

Contributors:
Preface

The 2021 Benchmarking report is the 17th collaborative effort highlighting environmental performance and progress in the nation’s electric power sector. The Benchmarking series began in 1997 and uses publicly reported data to compare the emissions performance of the 100 largest power producers in the United States. The company rankings are based on 2019 generation and emissions data and aggregate industry trends are presented through 2020.

Data on U.S. power plant generation and air emissions are available to the public through several databases maintained by state and federal agencies. Publicly- and privately-owned electric generating companies are required to report fuel and generation data to the U.S. Energy Information Administration (EIA). Most power producers are also required to report air pollutant emissions data to the U.S. Environmental Protection Agency (EPA). These data are reported and recorded at the boiler, generator, or plant level, and must be combined and presented so that company-level comparisons can be made across the industry.

The Benchmarking report facilitates the comparison of emissions performance by combining generation and fuel consumption data compiled by EIA with emissions data on sulfur dioxide (SO₂), nitrogen oxides (NOx), carbon dioxide (CO₂) and mercury (Hg) compiled by EPA; error checking the data; and presenting emissions information for the nation’s 100 largest power producers in a graphic format that aids in understanding and evaluating the data. The report is intended for a wide audience, including electric industry executives, environmental advocates, financial analysts, investors, journalists, power plant managers, and public policymakers.

Report Authors: Christopher Van Atten, Amlan Saha, Luke Hellgren, Ted Langlois

Plant and company level data used in this report are available at www.mjbradley.com.
Key Findings

• The 100 largest power producers in the United States own nearly 3,500 power plants and account for more than 80 percent of the sector’s electric generation and reported air emissions. Their fuel mix, emissions, and emission rates vary widely as summarized throughout this report (based on 2019 data).

• For the electric sector overall, in 2020, power plant SO$_2$ and NOx emissions were 95 percent and 88 percent lower, respectively, than in 1990 when Congress passed major amendments to the Clean Air Act. In 2020, power plant SO$_2$ and NOx emissions were 18 percent and 15 percent lower than they were in 2019.

• Power sector CO$_2$ emissions decreased about 10 percent between 2019 and 2020. In 2020, power plant CO$_2$ emissions were 20 percent lower than 1990 levels, and about 40 percent lower than their peak in 2007. Some of the factors driving this longer-term trend include energy efficiency improvements and the displacement of coal by natural gas and renewable energy resources.

• Mercury air emissions from power plants (as reported to the TRI database) have decreased 92 percent since 2000. The first-ever federal limits on mercury and other hazardous air pollutants from coal-fired power plants went into effect in 2015.

Electricity in the United States

The electricity sector in the United States includes a wide array of companies that produce and distribute electricity to homes and offices, industrial facilities, and other customers. The services it provides are essential to the growth and functioning of the U.S. economy. Electricity is expected to serve a growing share of energy consumption in the U.S. with the electrification of transportation and other end-uses.
Benchmarking Analytical Resources

The Benchmarking Report now includes a series of interactive, web-based dashboards to further visualize the emissions and electricity generation from power producers in the United States. These tools provide insight into how facility- and company-level emissions and generation are changing over time by utilizing historical Benchmarking data (2008-2019). Data include:

**Environmental**: Company-specific emissions and emission rates by company type and pollutant

**Operational**: Electricity generation and relevant data aggregated by company type, company, and other metrics

**Locational**: Facility-level emissions and generation visualized by fuel type, company ownership, and other metrics

These tools are available at [www.mjbradley.com](http://www.mjbradley.com).
Section I

U.S. Electric Sector Highlights
• In 2020, the U.S. electric system continued its general shift away from coal toward lower- and zero-emitting sources. For the fourth consecutive year, natural gas was the leading source of electricity generation in the U.S. (40 percent), followed by nuclear (20 percent).

• Coal plants accounted for 19 percent of total U.S. generation, hydroelectric resources 7 percent, and oil-fired resources <1 percent. Non-hydroelectric renewables (wind, solar, and geothermal) accounted for 11 percent of total U.S. generation (increasing from 9 percent in 2019).

• Other fuel sources such as biomass, municipal solid waste, tire-derived fuel, manufactured and waste gases, etc., accounted for less than 2 percent.

• This is a significant shift from the generation mix a decade ago. In 2006, coal accounted for 49 percent of power production, while natural gas generated only 20 percent.

Zero-Carbon Generation in the United States*
In 2020, renewables and other zero-carbon resources generated approximately 38% of U.S. electricity, making the combined category the second-leading source of power generation in the United States. Of the zero-carbon resources, nuclear made up 52%, renewables 29% (wind, solar, geothermal), and hydro 19%.

* Includes generation from utility-scale facilities only; distributed generation not included
Share of Emissions: U.S. Electric Sector and Other Sectors

% Share of Air Emissions

Benchmarking Air Emissions of the 100 Largest Electric Power Producers in the United States

July 2021
Section II

Emissions of the 100 Largest Electric Power Producers
## The 100 Largest Electric Power Producers

The report examines and compares the stack air pollutant emissions of the 100 largest power producers in the United States based on their 2019 generation, plant ownership, and emissions data. The table below lists the 100 largest power producers featured in this report ranked by their total electricity generation from fossil fuel, nuclear, and renewable energy facilities. These producers include public and private entities (collectively referred to as “companies” or “producers” in this report) that own nearly 3,500 power plants and account for 82 percent of reported electric generation and 81 percent of the industry’s reported emissions.

The report focuses on four power plant pollutants for which public emissions data are available: sulfur dioxide (SO2), nitrogen oxides (NOx), mercury (Hg), and carbon dioxide (CO2). At sufficient concentrations, these pollutants are associated with significant environmental and public health problems, including acid deposition, mercury deposition, nitrogen deposition, global warming, ground-level ozone, regional haze, and/or fine particle air pollution, which can lead to asthma and other respiratory illnesses. The report benchmarks, or ranks, each company’s absolute emissions and its emission rate (determined by dividing emissions by electricity produced) for each pollutant. In 2019, the 100 largest power producers emitted in aggregate approximately 0.96 million tons of SO2, 0.88 million tons of NOx, 3.63 tons of mercury, and 1.78 billion tons of CO2.

July 2021
85 of the Top 100 power producers generated power from zero-carbon resources in 2019, accounting for 83 percent of the national total generated from resources including nuclear, hydro, and renewables.
Important Note on Emission Rankings

The Benchmarking Report presents generation and emissions information of power producers, not distribution utilities that deliver electricity to customers. In order to apply a uniform methodology to all power producers, the Report assigns electricity generation and associated emissions to power producers according to their known generating asset ownership as of December 31, 2019. Assets retired or sold before this date are not allocated to power producers on a prorated basis. For example, a company which retires a generating unit before this date will not see its generation reflected in the rankings. Similarly, company which purchases a generating unit from another will take on the unit’s full output for the calendar year.

The above is true even when a producer’s generating facilities are part of one or more contractual agreements (e.g., power purchase contracts, etc.) with other entities (often utilities). In other words, this Report attributes all generation and emissions to the owner of an asset, not to purchasers of the asset’s output or to counterparties to the contracts. Publicly available data do not allow the accurate and exhaustive tracking of such agreements.

There are a host of reasons why a company’s generation profile may differ from that of the electricity it delivers to customers. For example, rural cooperatives, which are non-profit entities and are thus generally unable to directly take advantage of renewable tax credits, tend to rely on power purchase agreements and other non-asset owning mechanisms to deliver renewable electricity to their customers.

A vertically integrated utility that owns a large fossil generating fleet, but also delivers purchased renewable electricity to its customers, might have lower average emission rates than the level attributed in this report to the power producer that owns the said fossil fleet, if the renewable energy purchases were factored into the utility’s performance. By the same token, the utility’s emissions or emission rate would increase if it contracted with a higher emitting facility or relied on market purchases with associated emissions.

The charts in the next few slides present both the total emissions by company as well as their average emission rates. The evaluation of emissions performance by both emission levels and emission rates provides a more complete picture of relative emissions performance than viewing these measures in isolation. Total emission levels are useful for understanding each producer’s contribution to overall emissions loading, while emission rates are useful for assessing how electric power producers compare according to emissions per unit of energy produced when size is eliminated as a performance factor.

The charts illustrate significant differences in the total emission levels and emission rates of the 100 largest power producers. For example, CO\textsubscript{2} emissions range from zero to over 109 million short tons per year. The NO\textsubscript{x} emission rates range from zero to 2.4 pounds per megawatt-hour of generation. A power producer’s total emissions are influenced by the amount of generation that the producer owns and by the fuels and technologies that it uses to generate electricity.
Air pollution emissions from power plants are highly concentrated among a small number of producers. For example, nearly a quarter of the electric power industry’s SO₂ and CO₂ emissions are emitted by just three and five top 100 producers, respectively.
SO₂: Total Emissions and Emission Rates

Sorted from highest to lowest by emissions

Note: 12 companies report zero SO₂ emissions*

(Top 20 Privately-/Investor-Owned Power Producers)

**Note:** “Privately/investor owned” power producers include investor owned, privately held, and foreign owned corporations. This chart does not show public power producers (federal power authorities, state power authorities, municipalities, power districts) or cooperatives.
Section III

Emissions Trends Analysis
Annual Trends: U.S. Electric Sector

The electric power sector has made significant progress in terms of reducing its NOx and SO\textsubscript{2} emissions. From 2000 through 2020, NOx and SO\textsubscript{2} emissions decreased 85 and 93 percent, respectively. From 2000 to 2020, CO\textsubscript{2} emissions decreased 37 percent while GDP grew 40 percent. Over the same period, generation from renewables more than doubled.\textsuperscript{5}

Average Capacity Factors

Annual Capacity Factors for Select Fuels and Technologies

Capacity factors measure the extent to which a power plant is utilized over the course of time. The technical definition is the ratio of the electrical energy produced by a generating unit to the electrical energy that could have been produced assuming continuous full power operation.

Coal plant utilization has declined in recent years; the average annual capacity factor of coal plants in the U.S. dropped from 64 percent in 2009 to 40 percent in 2020, while over the same time period, natural gas combined-cycle capacity factors rose from 44 to 57 percent.

Nuclear plants have high utilization rates, consistently running at above 90 percent average capacity factor. Hydropower capacity factors have remained relatively constant over the past decade.

Wind capacity factors have increased from 28 percent in 2009 to 35 percent in 2020, largely due to improvements in wind turbine technology. Since EIA began publishing data for utility-scale solar projects in 2014, annual capacity factors have remained steady at around 25-26 percent.

In 2021, the International Energy Agency (IEA) released a report titled *Net Zero by 2050: A Roadmap for the Global Energy Sector*. The special report details a comprehensive pathway to achieve a net zero emissions energy system, guarantee reliable and affordable electricity globally, and limit long-term increase in global temperatures to 1.5 °C.

The achievements laid out in the report necessitate a complete transformation of the global energy system, which includes annual additions of 630 GW of solar PV and 390 GW of wind by 2030 – a rate equivalent to four times the record levels set in 2020. Electric vehicles constitute 60 percent of global car sales by 2030, and major innovations are required in direct air capture, hydrogen electrolysis, and advanced batteries.

Fossil fuel production and use are drastically reduced over the 30-year time period. After 2021, no new oil and gas fields are approved for development – producers empty out reserves. Gas demand declines 55 percent and oil demand declines 75 percent by 2050 globally.

Electricity provides 50 percent of total energy consumption in 2050, with 90 percent coming from renewable sources.
In the Net Zero Emissions Scenario (NZE), total electricity demand grows 40 percent to 2030 and 150 percent by 2050. In advanced economies, emissions from generation reach net zero by 2035 and globally by 2040. Electricity production by coal declines sharply and in 2050, 80 percent of coal-fired generation facilities use carbon capture and storage. Renewables increase from 29 percent of generation in 2020 to 60 percent in 2030 and 90 percent in 2050. Solar becomes the largest source of renewables in terms of installed capacity and total annual energy investment reaches $5 trillion by 2030.
Section IV

State-by-State Emissions Summary
## State-by-State \( \text{CO}_2 \) Emissions: U.S. Electric Sector, 2019

### Total \( \text{CO}_2 \) Emissions by State

Section VI

Appendix
Ranking Utility Portfolios

- As described above, the Benchmarking Report presents generation and emissions information of power producers, not utility companies with obligations to deliver electricity to customers. In order to apply a uniform methodology to all power producers, the Report assigns electricity generation and associated emissions to power producers according to their known generating asset ownership as of December 31, 2019.

- If a power producer is also a distribution utility, the fuel mix and emissions associated with the utility’s total supply portfolio may differ substantially from its owned generation, depending on the nature and extent of any power purchase agreements and other contractual agreements to which the utility may be party. The distribution utility might also rely on market purchases to supply its customers (e.g., purchases from the PJM or MISO markets). A power producer might also sell excess supply to the market or to other utilities.

- To highlight the potential implications of these two different approaches, the following slides present the generation mix and all-source CO₂ emission rate for a rural electric cooperative (Great River Energy) and investor-owned utility (Xcel). The graph also reports the CO₂ emission rate associated with part of the company’s supply portfolio (owned generation and long-term contracts); the supply portfolio emission rate does not reflect the emissions associated with market purchases, which may be fossil-fired, renewables, or other sources.

- In the examples shown, the CO₂ emission rate associated with supply is lower because both companies contract for non-emitting, renewable resources in addition to owned wind or solar projects (Great River Energy only owns fossil assets). Rural cooperatives are non-profit entities that are generally unable to take advantage of renewable tax credits, so they will tend to purchase renewable energy under long-term contracts rather than owning the facilities.

- Both approaches—generation and supply—can be helpful in evaluating a company’s performance. Unfortunately, there is no publicly available source for the data that would be required to benchmark utility resource portfolios in the same way that we can benchmark owned-generation assets.

- The following slides illustrate the all-source CO₂ emissions rates for Great River Energy and Xcel. The companies voluntarily supplied the information displayed. The charts include the emission rate for owned generation only (consistent with the focus and methodology of the Benchmarking report) as well as the all-source emission rate associated with the combination of owned generation and long-term contract purchases.

Note: contracted power includes long-term PPAs, and short-term and spot market purchases

Xcel Energy's All Source CO₂ Emission Rate decreases 22% when factoring in owned generation and contracted supply (both fossil and zero-emitting)
Data Sources

The following public data sources were used to develop this report:

EPA AIR MARKETS PROGRAM DATA (AMP): EPA’s Air Markets Program Data account for almost all of the SO₂ and NOx emissions, and about 20 percent of the CO₂ emissions analyzed in this report.

EPA TOXIC RELEASE INVENTORY (TRI): The 2019 mercury emissions used in this report are based on TRI reports submitted by facility managers.

EIA FORMS 923 POWER PLANT DATABASES (2019): EIA Form 923 provides data on the electric generation and heat input by fuel type for utility and non-utility power plants. The heat input data was used to calculate approximately 80 percent of the CO₂ emissions analyzed in this report.

EIA FORM 860 ANNUAL ELECTRIC GENERATOR REPORT (2019): EIA Form 860 is a generating unit level data source that includes information about generators at electric power plants, including information about generator ownership.

EPA U.S. INVENTORY OF GREENHOUSE GAS EMISSIONS AND SINKS (2019): EPA’s U.S. Inventory of Greenhouse Gas Emissions and Sinks report provides in Annex 2 heat contents and carbon content coefficients of various fuel types. This data was used in conjunction with EIA Form 923 to calculate approximately 20 percent of the CO₂ emissions analyzed in this report.
Methodology

Plant Ownership

This report aims to reflect power plant ownership as of December 31, 2019. Plant ownership data used in this report are primarily based on the EIA-860 database from the year 2019. EIA-860 includes ownership information on generators at electric power plants owned or operated by electric utilities and non-utilities, which include independent power producers, combined heat and power producers, and other industrial organizations. It is published annually by EIA.

For the largest 100 power producers, plant ownership is further checked against self-reported data from the producer’s 10-K form filed with the SEC, listings on their website, and other media sources. Ownership of plants is updated based on the most recent data available. Consequently, in a number of instances, ultimate assignment of plant ownership in this report differs from EIA-860’s reported ownership. This primarily happens when the plant in question falls in one or more of the categories listed below:

1. It is owned by a limited liability partnership of shareholders of which are among the 100 largest power producers.
2. The owner of the plant as listed in EIA-860 is a subsidiary of a company that is among the 100 largest power producers.
3. It was sold or bought during the year 2019. Because form 10-K for a particular year is usually filed by the producer in the first quarter of the following year, this report assumes that ownership as reported in form 10-K is more accurate.

Publicly available data do not provide a straightforward means to accurately track lease arrangements and power purchase agreements. Therefore, in order to apply a standardized methodology to all companies, this report allocates generation and any associated emissions according to reported asset ownership as of December 31, 2019.

Identifying “who owns what” in the dynamic electricity generation industry is probably the single most difficult and complex part of this report. In addition to the categories listed above, shares of power plants are regularly traded and producers merge, reorganize, or cease operations altogether. While considerable effort was expended in ensuring the accuracy of ownership information reflected in this report, there may be inadvertent errors in the assignment of ownership for some plants where public information was either not current or could not be verified.

Generation Data and Cogeneration Facilities

Plant generation data used in this report come from EIA Form 923.

Cogeneration facilities produce both electricity and steam or some other form of useful energy. Because electricity is only a partial output of these plants, their reported emissions data generally overstate the emissions associated with electricity generation. Generation and emissions data included in this report for cogeneration facilities have been adjusted to reflect only their electricity generation. For all such cogeneration facilities emissions data were calculated on the basis of heat input of fuel associated with electricity generation only. Consequently, for all such facilities EIA Form 923, which report a plant’s total heat input as well as that which is associated with electricity production only, was used to calculate their emissions.
Methodology (continued)

**NOx and SO\(_2\) Emissions**

The EPA AMP database collects and reports SO\(_2\) and NOx emissions data for nearly all major power plants in the U.S. Emissions information reported in the AMP database is collected from continuous emission monitoring (CEM) systems. SO\(_2\) and NOx emissions data reported to the AMP account for all of the SO\(_2\) and NOx emissions assigned to the 100 largest power producers in this report.

The AMP database collects and reports SO\(_2\) and NOx emissions data by fuel type at the boiler level. This report consolidates this data at the generating unit and plant levels. In the case of jointly owned plants, because joint ownership is determined by producer’s share of installed capacity, assignment of SO\(_2\) and NOx emissions to the producers on this basis implicitly assumes that emission rates are uniform across the different units. This may cause producers to be assigned emission figures that are slightly higher or lower than their actual shares.

The appointment of NOx emissions between coal and natural gas at boilers that can burn both fuels may in certain instances slightly overstate coal’s share of the emissions. This situation is likely to arise when a dual-fuel boiler that is classified as “coal-fired” within AMP burns natural gas to produce electricity in substantial amounts. In most years there would be very little economic reason to make this switch in a boiler that is not part of a combined cycle setup. Continued low natural gas prices in 2017 led to a small number of boilers switching to natural gas for most or a large part of their electricity output. Because AMP datasets do not make this distinction, apportioning emissions based on the fuel-type of the boiler would increase coal’s share of emissions.

SO\(_2\) and CO\(_2\) emissions are mostly not affected by this issue. Natural gas emits virtually no SO\(_2\). CO\(_2\) emissions can be calculated from the heat input data reported in EIA Form 923, which allows for the correct apportionment of emissions between coal and natural gas.

**CO\(_2\) Emissions**

A majority of CO\(_2\) emissions used in this report were calculated using heat input data from EIA form 923 and carbon content coefficients of various fuel types provided by EPA. The table on the following slide shows the carbon coefficients used in this procedure. Non-emitting fuel types, whose carbon coefficients are zero, are not shown in the table. CO\(_2\) emissions reported through the EPA AMP account for a small share of the CO\(_2\) emissions used in this report.

The datasets report heat input and emissions data by fuel type at either the prime mover or boiler level. This report consolidates that data at the generating unit and plant levels. In the case of jointly owned plants, because joint ownership is determined by producer’s share of installed capacity, assignment of CO\(_2\) emissions to the producers on this basis implicitly assumes that emission rates are uniform across the different units. This may cause producers to be assigned emission figures that are slightly higher or lower than their actual shares.

**Mercury Emissions**

Mercury emissions data for coal power plants presented in this report were obtained from EPA’s Toxic Release Inventory (TRI). Mercury emissions reported to the TRI are based on emission factors, mass balance calculations, or data monitoring. The TRI contains facility-level information on the use and environmental release of chemicals classified as toxic under the Clean Air Act. The TRI contains information on all toxic releases from a facility; mercury emissions in this report are based on air releases only. Because coal plants are the primary source of mercury emissions within the electric industry, the mercury emissions and emission rates presented in this report reflect the emissions associated with each producer’s fleet of coal plants only.

Quality Assurance

This report examines the air pollutant emissions of the 100 largest electricity generating companies in the United States based on 2019 electricity generation, emissions, and ownership data. The report relies on publicly-available information reported by the U.S. Energy Information Administration (EIA), U.S. Environmental Protection Agency (EPA), Securities and Exchange Commission (SEC), state environmental agencies, company websites, and media articles. Emission data may include revisions to 2019 data that companies were in the process of submitting or have already submitted to EPA at the time of publication of this report.

This report relies almost entirely on publicly available information. Data sets published by EIA and EPA are the primary source of the generation and emissions data used in this report. The organizations that fund this report believe maintaining public access to this information is essential to tracking the industry's performance and making accurate and informed analyses and policy decisions.
Endnotes

1. Private entities include investor-owned and privately held utilities and non-utility power producers (e.g., independent power producers). Cooperative electric utilities are owned by their members (i.e., the consumers they serve). Publicly-owned electric utilities are nonprofit government entities that are organized at either the local or State level. There are also several Federal electric utilities in the United States, such as the Tennessee Valley Authority.

Power plant ownership in this report is divided into three categories: privately/investor owned (investor-owned corporations, privately held corporations, foreign-owned corporations), public power (federal power authorities, state power authorities, municipalities, power districts), and cooperative.

3. Generation data from EIA Monthly Energy Review Table 7.2a Electricity Generation Total for All Sectors available at https://www.eia.gov/totalenergy/data/monthly/#electricity

5. The sources used in the Annual Trends figure have already made national-level 2020 data available, allowing the trends section to extend through 2020. Detailed 2020 data used for the company-specific analysis of the top 100 electricity producers was not yet available at the time of report publication.
